1. Supervised learning
    a. Features could be "computation power" and "energy use"
    b. The two labels are "robot" and "non-robot"
2. a, c
3. conditional probability
    a. Given the knowledge that both classes occur with the same frequency, we can simply look at the graph and see that C2 occurs with higher P(X|C) at the data point because it scores a higher $P(x|C_2)$
    b. With $P(C_1) = 0.9$, then it changes to C1 because there is a much higher chance of C1 occurring For C1, we have 0.13 * 0.9 = 0.117 and for C2 we have 0.33 * 0.1 = 0.033. So we choose C1 which has a higher prior times likelihood
